In **Tableau**, a **Calculated Field** is a custom field you create using formulas to perform computations on your data. It allows you to go beyond the raw fields in your dataset and generate new metrics or dimensions. For example, you might calculate **BMI categories, risk scores, or percentage changes**.

You can create a calculated field in Tableau by:

Right-clicking on the data pane and selecting **Create → Calculated Field**.

Giving it a name.

Writing your formula (e.g., IF [Cholesterol] > 200 THEN "High" ELSE "Normal" END).

Clicking **OK**, after which the new field appears in your data pane.

In our project, we **have not created any calculated fields**, but you can create them according to the specific insights you want, such as **risk group classifications, ratios, or derived health metrics**.

SOLUTION—

1. Open Tableau Public and load the dataset (Heart_Cleaned.csv).
2. Go to the worksheet where the data fields are displayed in the Data Pane.
3. Right-click in the Data Pane and select **Create → Calculated Field**.
4. Enter the name of the calculated field (e.g., BMI Category).
5. Write the formula using existing dataset fields.

6. Click **OK** to create the calculated field.
7. The new calculated field will appear in the Data Pane.
8. Repeat the same process to create other calculated fields such as Health Risk and Physical Health Status.
9. These calculated fields help derive new insights from the dataset.
10. The calculated fields can be used in charts and dashboards for better analysis.
